This article provides a comprehensive review of programming FEM in MATLAB, offering insights into core concepts, implementation strategies, and best practices to harness the full potential of this synergy.

## Understanding the Finite Element Method (FEM)

### Fundamental Principles of FEM

FEM is a numerical technique that subdivides a complex domain into smaller, manageable units called finite elements. These elements are interconnected at points known as nodes. By approximating the unknown field variables (such as displacement, temperature, or pressure) within each element using shape functions, FEM transforms a continuous problem into a discrete system of equations solvable by computational means.

Key steps in FEM include:

- Discretization of the Domain: Dividing the problem domain into finite elements (triangles, quadrilaterals, tetrahedra, etc.).
- Selection of Shape Functions: Choosing polynomial functions that interpolate the solution within each element.
- Formulation of Element Equations: Deriving local stiffness matrices or other relevant operators based on governing equations.

- Assembly of Global System: Combining all element equations into a global matrix system that embodies the entire problem.
- Application of Boundary Conditions: Incorporating physical constraints and known values.
- Solution of the System: Solving the algebraic equations for unknown nodal values.
- Post-processing: Interpreting the results for analysis, visualization, or further computation.

## Why Use MATLAB for FEM?

MATLAB's environment provides a fertile ground for implementing FEM due to its:

- Matrix-oriented operations facilitating efficient assembly and solution procedures.
- Ease of coding with straightforward syntax for handling complex data structures.
- Built-in visualization tools for plotting meshes, deformations, and field variables.
- Extensive libraries and community support for numerical methods.
- Rapid prototyping capabilities enabling quick development and testing of algorithms.

## Implementing FEM in MATLAB: Step-by-Step Approach

Developing a finite element solver in MATLAB involves several core modules, each requiring careful implementation to ensure accuracy and efficiency.

### 1. Mesh Generation

The initial step involves subdividing the problem domain into finite elements. MATLAB offers various tools for mesh generation, such as the PDE Toolbox, or users can write custom scripts.

- Manual Mesh Creation: For simple geometries, define node coordinates and element connectivity matrices directly.
- Using PDE Toolbox: Functions like `generateMesh` automate the meshing process, especially for complex geometries.

An example of manually defining a simple 2D mesh:

```
```matlab
```

```
% Define nodes
```

```
nodes = [0 0; 1 0; 1 1; 0 1];
```

```
% Define elements (triangles)
```

```
elements = [1 2 3; 1 3 4];
```

```
...
```

## 2. Defining Shape Functions and Element Matrices

For linear triangular elements, shape functions are well-known and straightforward. The local stiffness matrix can be derived analytically or numerically.

For a linear triangular element:

- The shape functions  $\{N_i\}$  are linear functions associated with each node.
- The element stiffness matrix  $\{k_e\}$  can be computed via:

$$\{$$

$$k_e = \frac{A}{3} B^T D B$$

$$\}$$

where:

- $\{A\}$  is the area of the triangle.
- $\{B\}$  is the strain-displacement matrix.
- $\{D\}$  is the material property matrix (e.g., elasticity matrix for mechanics).

Implementation involves calculating these matrices for each element.

```
```matlab
```

```
% Example: compute local stiffness matrix for a triangular element
```

```
% Coordinates of the triangle's nodes
```

```
x = nodes(e,1);
```

```
y = nodes(e,2);
```

```

A = polyarea(x,y); % Area of the triangle

% Compute B matrix (strain-displacement)

% ... (code to compute B based on node coordinates)

% Compute local stiffness

k_e = (A/2) (B' D B);

...

```

### 3. Assembly of Global Matrices

Once local matrices are computed, assemble them into a global matrix that represents the entire domain.

- Initialize a sparse matrix for efficiency.
- Loop over each element, adding local matrices to the global matrix at positions corresponding to the nodes.

```

```matlab

K = sparse(numberOfNodes, numberOfNodes);

for e = 1:numberOfElements

nodes_e = elements(e, :);

K(nodes_e, nodes_e) = K(nodes_e, nodes_e) + k_e;

end

...

```

### 4. Applying Boundary Conditions

Physical constraints are enforced by modifying the global matrix and load vector.

- For Dirichlet boundary conditions, set the corresponding rows and columns to enforce known values.
- Adjust the load vector accordingly.

```
```matlab
```

```
% Example: fix node 1 at displacement zero
```

```
fixedNode = 1;
```

```
K(fixedNode, :) = 0;
```

```
K(:, fixedNode) = 0;
```

```
K(fixedNode, fixedNode) = 1;
```

```
F(fixedNode) = 0;
```

```
```
```

## 5. Solving the System

Use MATLAB's built-in solvers to compute nodal unknowns.

```
```matlab
```

```
displacements = K \ F;
```

```
```
```

## 6. Post-Processing and Visualization

Visualize results using MATLAB plotting functions.

```
```matlab
```

```
patch('Vertices', nodes, 'Faces', elements, ...
```

```
'FaceVertexCData', displacements, 'FaceColor', 'interp');
```

```
colorbar;
```

```
title('Displacement Field');
```

```
```
```
